Building Blocks

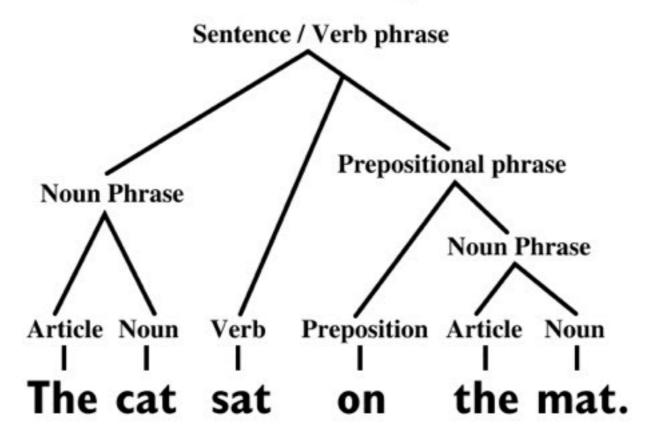

"to get a deeper understanding of the language"

Deep C - a 3 day course Jon Jagger & Olve Maudal

To get a deep understanding of any language you need to be able to 'break' it down and analyse it. You need to recognize the *words* used when experts are discussing among themselves.

Basic constituent structure analysis of a sentence:

```
pre-processor directive
function prototype
                            int printf(const char * restrict, ...);
                            void exit(Int);
     linkage
                                                                         declaration without
                            #define EXIT FAILURE 1
  specification
                                                                            initialization
                            static void say hello(const char * who
function definition
                                                                                comment
                                 printf("Hello %s\n", who);
   internal linkage
                                                                               comment
                            // compute the answer
                             in⇒ the_answer()
    external linkage
                                                                              expression
                               →register int a;
storage class specifier-
                              int b = 6; /* mystic base value
    declaration with
      initialization
                                 for (int i=0; 1<7.
                                  → a += b;
      expression statement-
                                                                              assignment
                               → return a;
           keyword
                                                                              expression
   type qualifier
                            const int life universe everything = 42;
                                                                             statement
                            int main(void)
        type specifier
                                                                            macro name
                                say_hello("everyone");
                                 int a = the_answer();
                                 if (a != life_universe_everything)
                                     exit(EXIT FAILURE);
```

```
if (answer < 0)
answer = 42;
```

this is what you see

```
lexical analyser
```

```
if
(
answer
<
0
)
answer
=
42
;</pre>
```

this is what the compiler sees

```
if (answer < 0)
answer = 42;
```

```
lexical analyser
```

There are 6 classes of tokens in a C program

keyword	if struct restrict
identifier	the_answer main i
constant	9 6f 013 '9' 9.6
string literal	"Hello"
operator	+ - * / % = , () []
punctuator	; = , { } () []

token examples

```
#include <stdio.h>
static int calc(int a, int b, int c)
    return a * b / c;
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
```

```
#include <stdio.h>
static int calc(int a, int b, int c)
    return a * b / c;
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
```

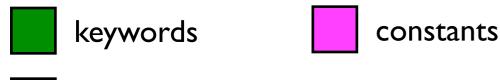

```
#include <stdio.h>
static int calc(int a, int b, int c)
    return a * b / c;
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
```

```
#include <stdio.h>
static int calc(int a, int b, int c)
    return a * b / c;
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
```

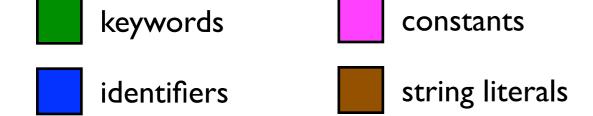

keywords

```
#include <stdio.h>
static int calc(int a, int b, int c)
    return a * b / c;
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
```

```
#include <stdio.h>

int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
   keywords
                constants
                             punctuators
```

string literals

```
#include <stdio.h>
static int calc(int a, int b, int c)
    return a * b / c;
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
    int a = calc(universe, life(), everything());
    printf("The answer is %d\n", a);
   keywords
                constants
                             punctuators
```

operators

string literals

```
but what about
#include <stdio.h>
                                 this one?
static int calc(int a)
                              this is a preprocessor directive, and is
                             not really part of the language. We will
     return a * b / c;
                                    deal with this later.
int universe = 7;
static int life(void) { return 6; }
int everything(void) { return 1; }
int main(void)
     int a = calc(universe, life(), everything());
     printf("The answer is %d\n", a);
   keywords
                   constants
                                  punctuators
```

Identifiers

Rules

- made of letters, digits and underscores
- can't start with a digit
- case sensitive

variable1 802id

Recommendations

- don't start with underscore (reserved)
- use case consistently
- avoid abbrs
- don't use klever spelling
- don't use hungarian

```
_variable
vrbls
iVariable
```

CamelCase
snake_case
mixedCase

```
int year = 1992;
if (is_leap_year(year))
    do_extra_maintainance();
```

```
int year = 1992;
if (IsLeapYear(year))
    DoExtraMaintainance();
```

```
int Year = 1992;
if (IsLeapYear(Year))
    do_extra_maintainance();
```

Identifiers

larger scope ← → longer identifier smaller scope ← → shorter identifier

```
for (size_t loop_index = 0; loop_index < 42; loop_index++)</pre>
    widgetize(wibbles[loop_index]);
                                                     better
for (size_t index = 0; index < 42; index++)</pre>
    widgetize(wibbles[index]);
                                           better
for (size_t at = 0; at < 42; at++)
    widgetize(wibbles[at]);
```

Quick... What does the following code print?

```
#include <stdio.h>
int main(void)
{
   int a = 44;
   a =- 2;
   printf("%d\n", a);
}
```

Quick... What does the following code print?

```
#include <stdio.h>
int main(void)
     int a = 44;
     a = - 2;
                                                                    this is what
     printf("%d\n", a);
                                                                    the compiler
                                             lexical analyser
                                                                    sees
                                                                    identifier a
                                                                    operator =
                                                                    operator -
    but you do get a warning from the
                                                                    constant 2
               compiler?
```

```
$ gcc foo.c && ./a.out
-2
$ gcc -Wall -Wextra -pedantic foo.c && ./a.out
-2
```
